While many frameworks use MVC (Model-View-Controller), Django uses a slightly different pattern called MVT (Model-View-Template).
Model: This is your data layer. Instead of writing complex SQL, you define your data structures as Python classes. Django's ORM (Object-Relational Mapper) then automatically translates that into database tables (PostgreSQL, MySQL, SQLite, etc.).
View: This is the logic layer. It's a Python function or class that receives a web request, interacts with the Model to get data, and then returns a response (usually by calling a Template).
Template: This is the presentation layer. It consists of HTML mixed with Django Template Language (DTL), which allows you to insert dynamic data (like a user's name or a list of blog posts) into the page.
